UNIVERSITY OF
OXFORD

(c) Interaction/"Merger"

- now within one halo, galaxies interact & lose angular momentum
- SFR starts to increase
- stellar winds dominate feedback
- rarely excite QSOs (only special orbits)

(b) "Small Group"

- halo accretes similar-mass companion(s)
- can occur over a wide mass range
- M_{halo} still similar to before: dynamical friction merges the subhalos efficiently

(a) Isolated Disk

- halo & disk grow, most stars formed
- secular growth builds bars & pseudobulges
- "Seyfert" fueling (AGN with $M_B > -23$)
- cannot redden to the red sequence

(d) Coalescence/(U)LIRG

- galaxies coalesce: violent relaxation in core
- gas inflows to center: starburst & buried (X-ray) AGN
- starburst dominates luminosity/feedback, but, total stellar mass formed is small

(e) "Blowout"

- BH grows rapidly: briefly dominates luminosity/feedback
- remaining dust/gas expelled
- get reddened (but not Type II) QSO: recent/ongoing SF in host
- high Eddington ratios
- merger signatures still visible

(f) Quasar

- dust removed: now a "traditional" QSO
- host morphology difficult to observe: tidal features fade rapidly
- characteristically blue/young spheroid

(g) Decay/K+A

- QSO luminosity fades rapidly
- tidal features visible only with very deep observations
- remnant reddens rapidly (E+A/K+A)
- "hot halo" from feedback
- sets up quasi-static cooling

(h) "Dead" Elliptical

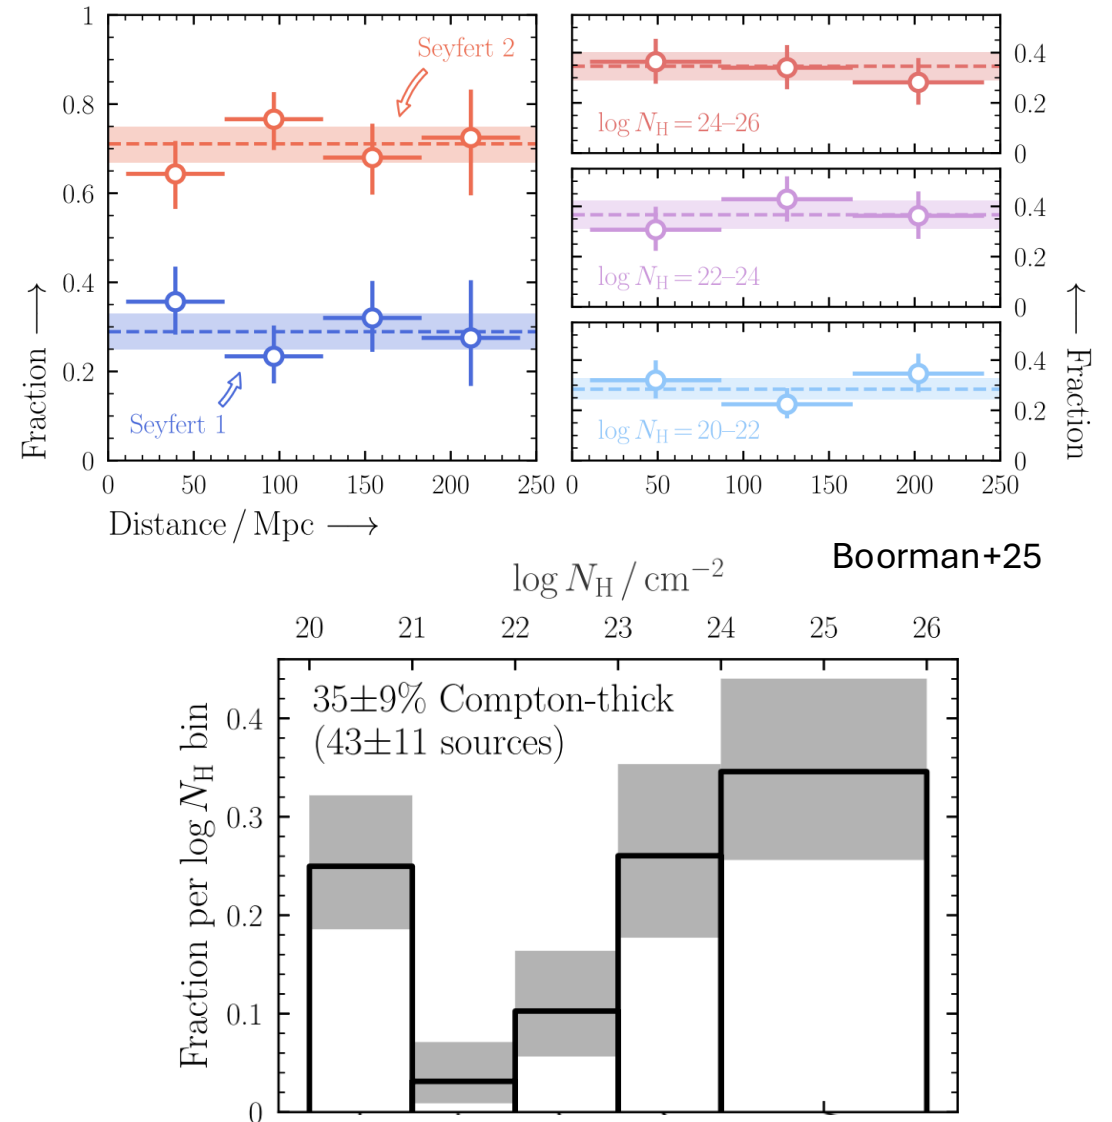

- star formation terminated
- large BH/spheroid - efficient feedback
- halo grows to "large group" scales: mergers become inefficient
- growth by "dry" mergers

Population of Obscured AGN: X-ray view

- Most AGN are Obscured!
- $\sim 70\%$ of AGN with $N_H > 10^{22} \text{ cm}^{-2}$
- $\sim 35\%$ of AGN are Compton Thick with $N_H > 10^{24} \text{ cm}^{-2}$
- Lack of sensitivity to detect photons behind $N_H \sim 10^{26} \text{ cm}^{-2}$ (Ricci+21)

Cosmic X-ray Background

Compact Obscured Nuclei (CONs)

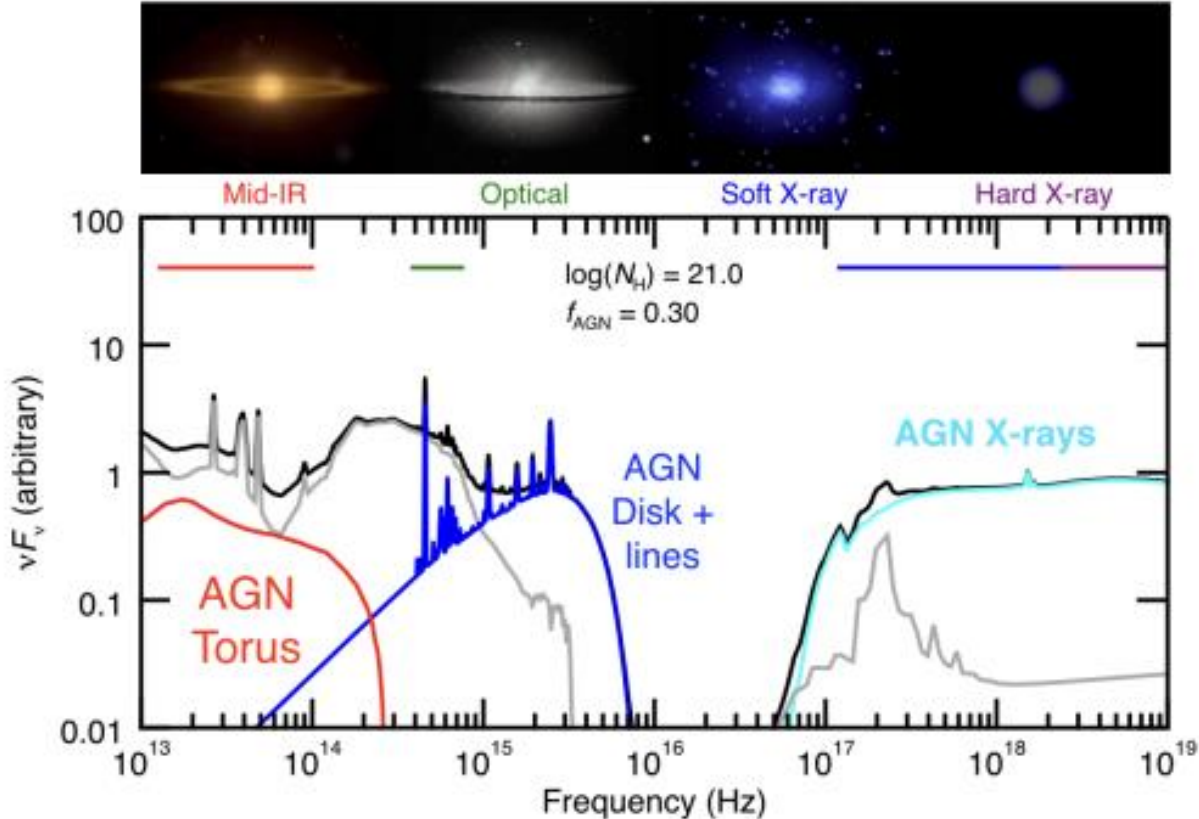

- Power Source (likely AGN) completely obscured by gas/dust ($N_H > 10^{25}$)
- Detected via dense gas tracers in mm (HCN-vib) (e.g. Aalto+15,19)
 - Very faint – even with ALMA
- 40% of local ULIRGs
 - Often major mergers

Garcia-Bernete adapted from Baba+22

What do Obscured AGN look like?

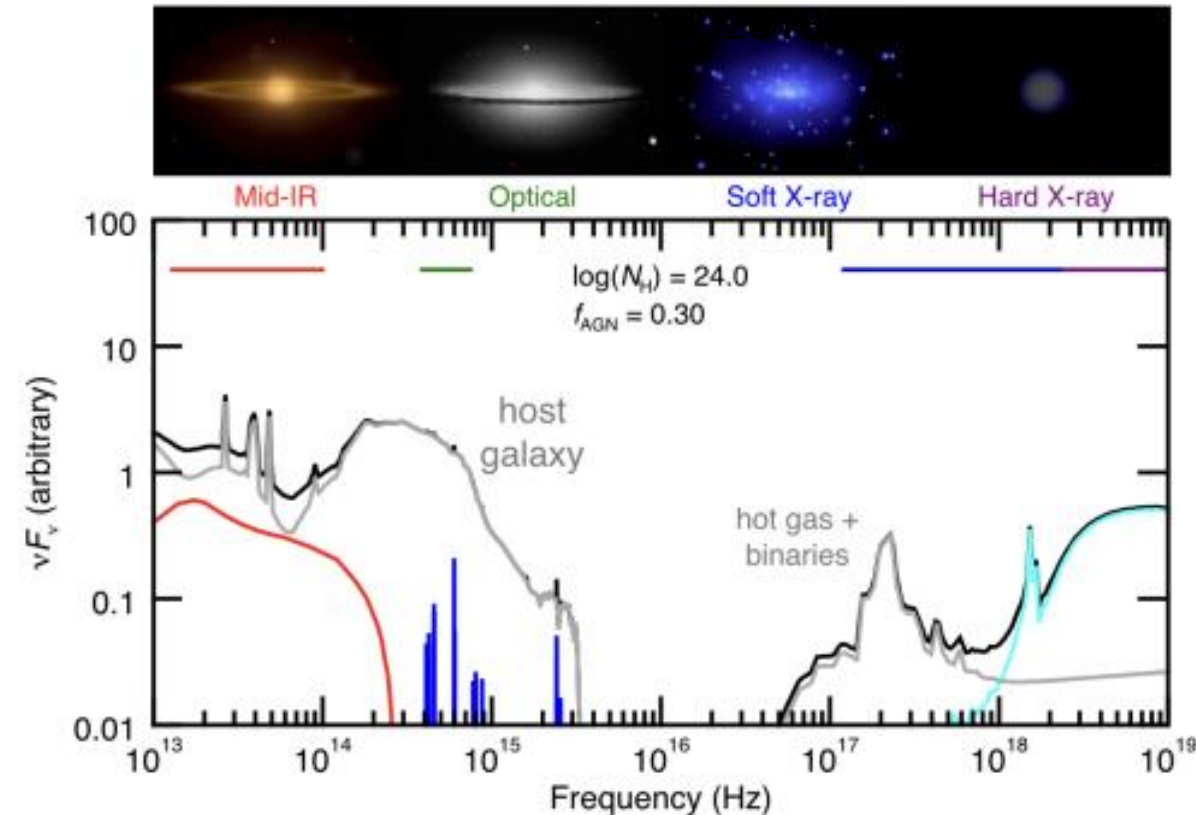

Unobscured

- Soft X-rays
- High Ionisation potential lines -> BPT diagram
- Broad H β lines -> BH Mass
- UV/Optical accretion disk continuum -> Accretion rate

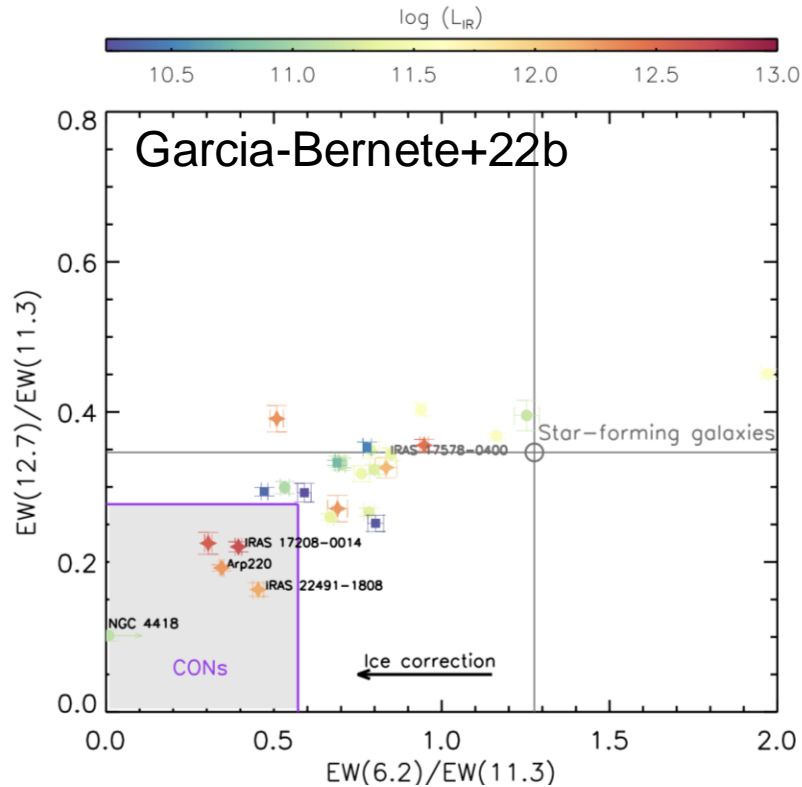

Obscured

Hickox & Alexander

- No photons escape – no high-IP lines
- Only mid-IR continuum

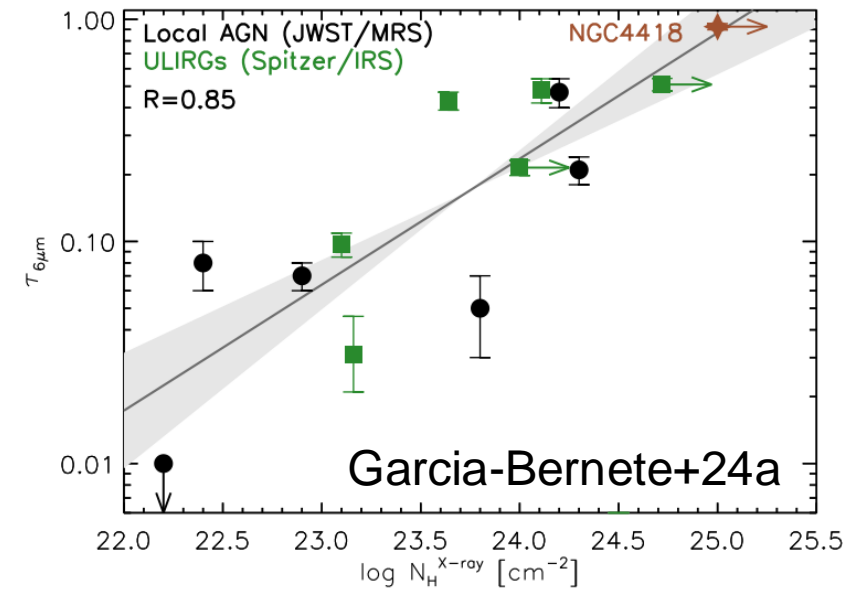

Mid-IR as a probe of obscured activity

- Select Highly Obscured Nuclei via PAH EW ratios

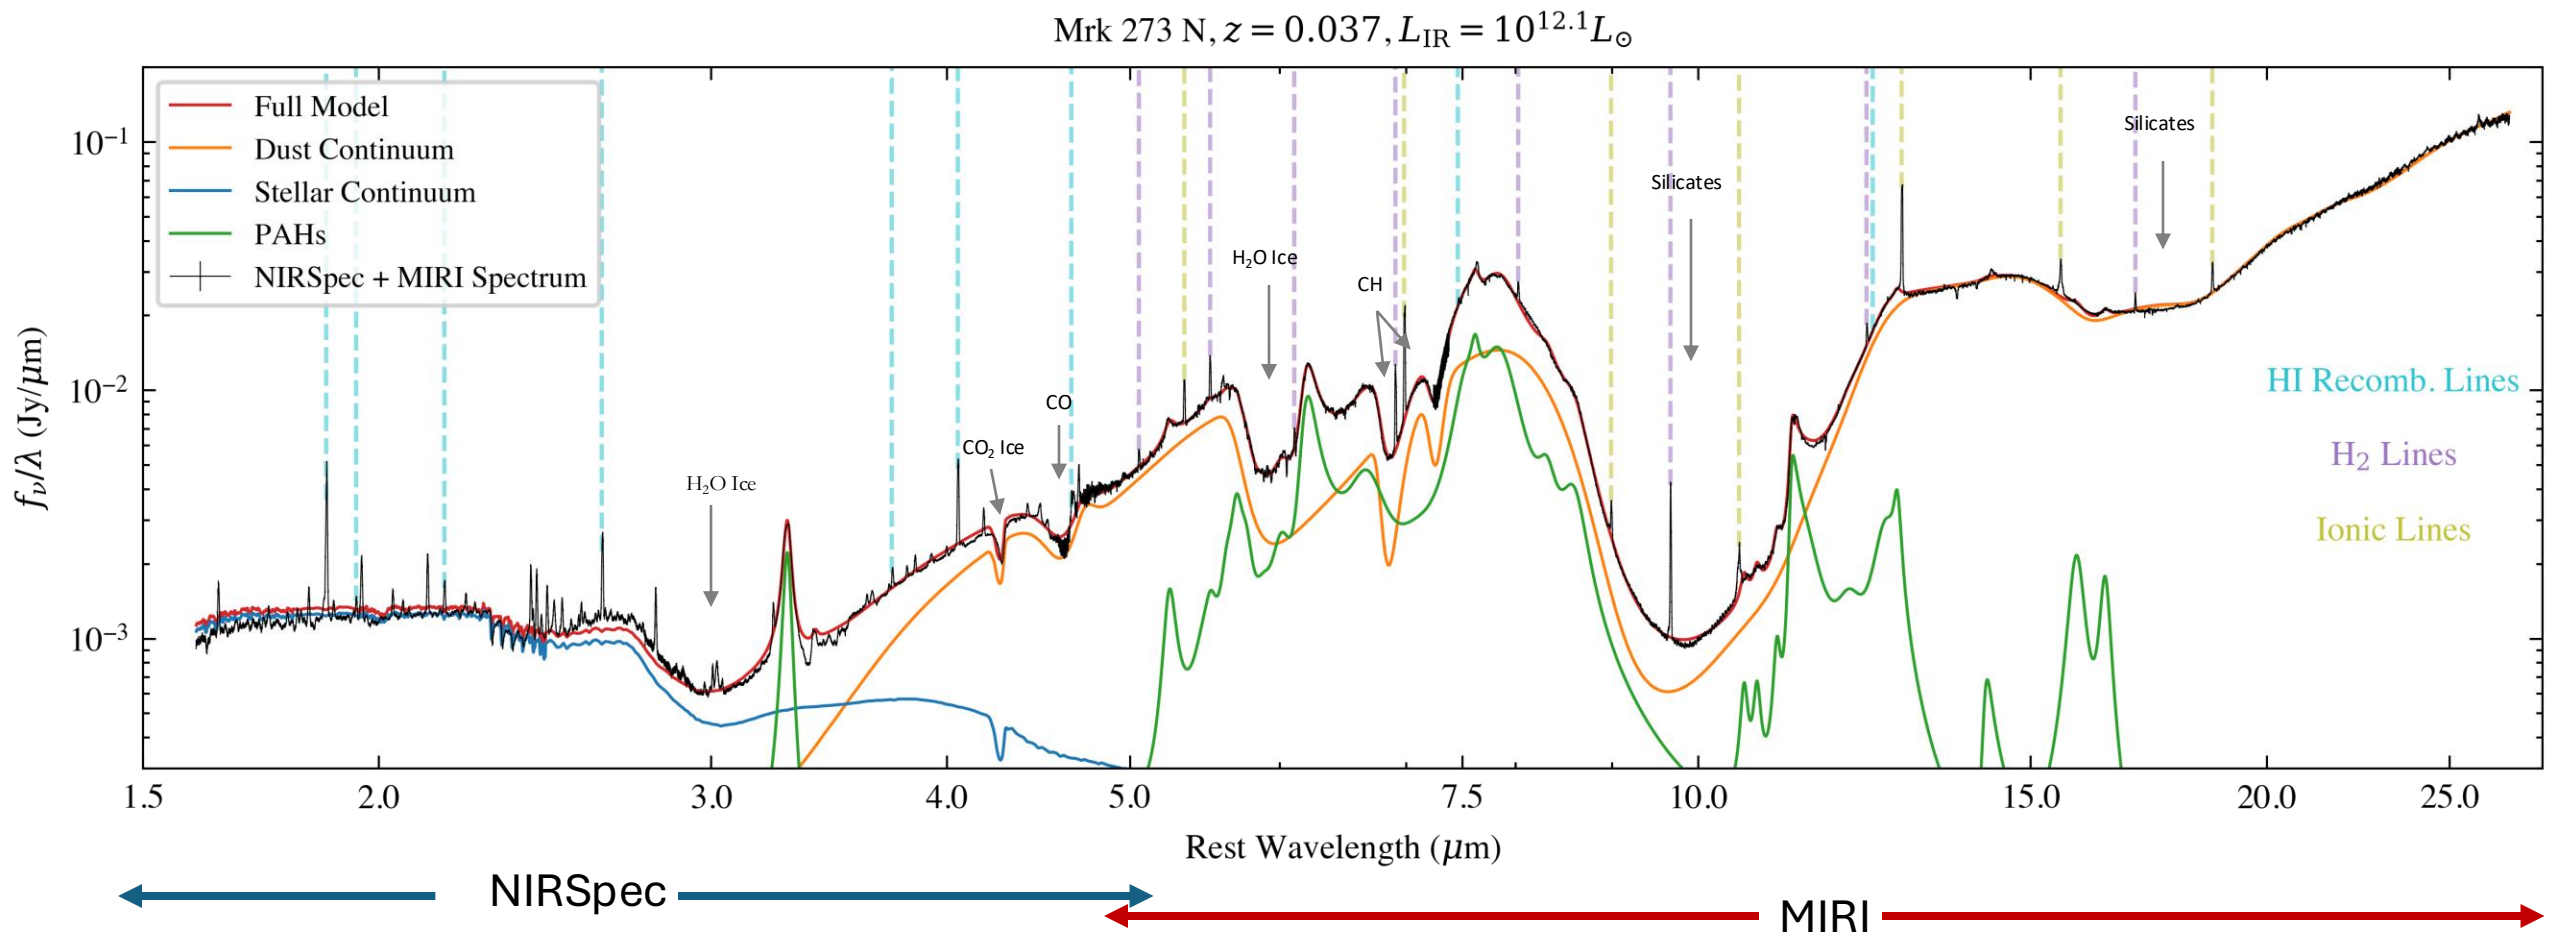

- Silicate depth traces HCN-vib surface brightness after accounting for SF dilution.

- H₂O Ice traces obscuration sequence from AGN to ULIRGs

JWST View

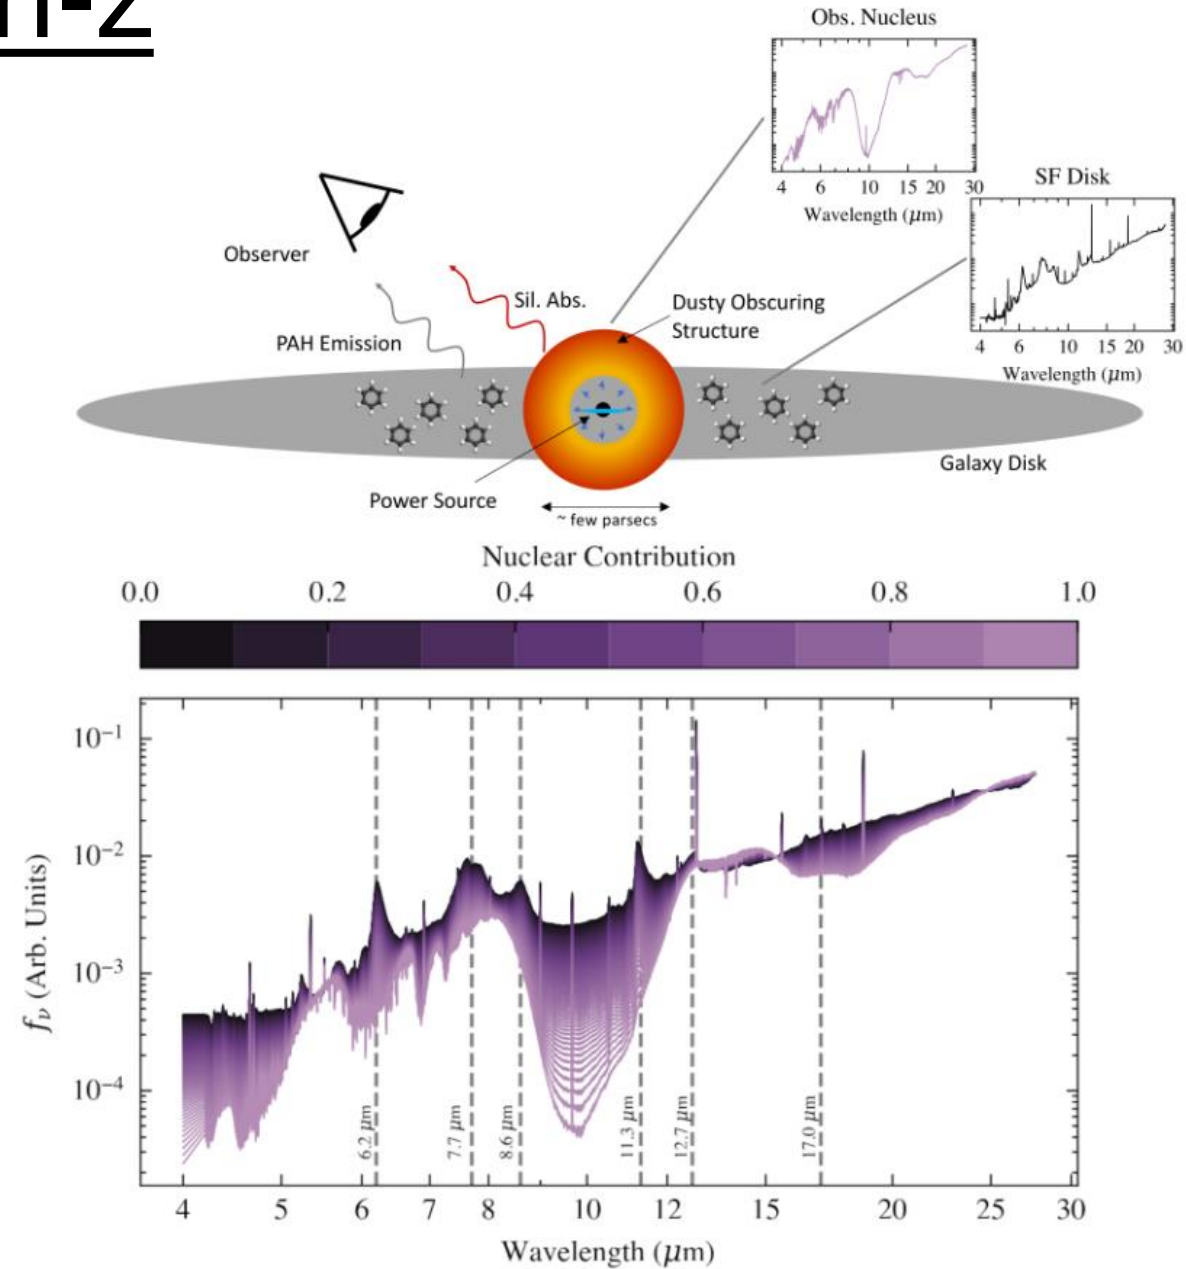

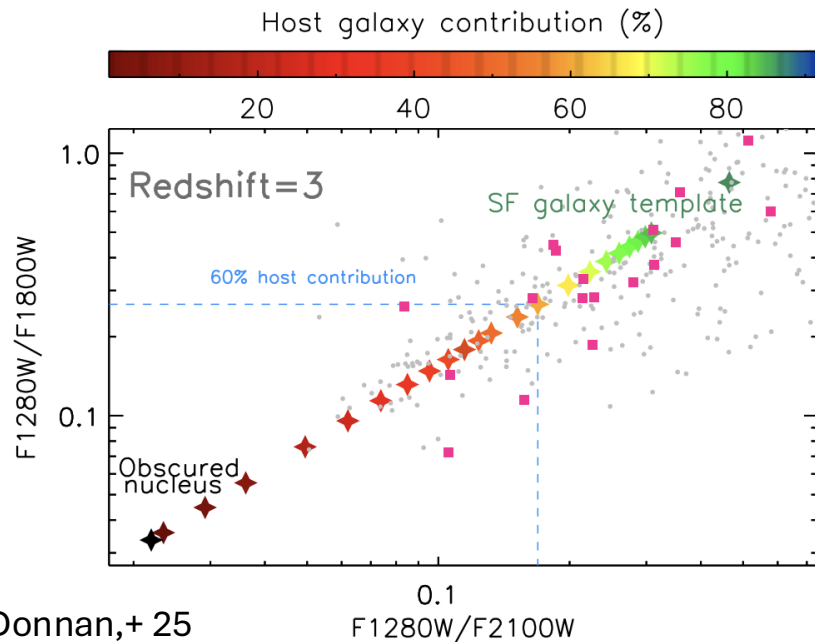

JWST View

- Cool dust continuum & deep silicates
- No high-IP lines
- No X-ray detections (Ricci+21)
- See also Donnan+23b, 24a

Obscured nuclei at high-z

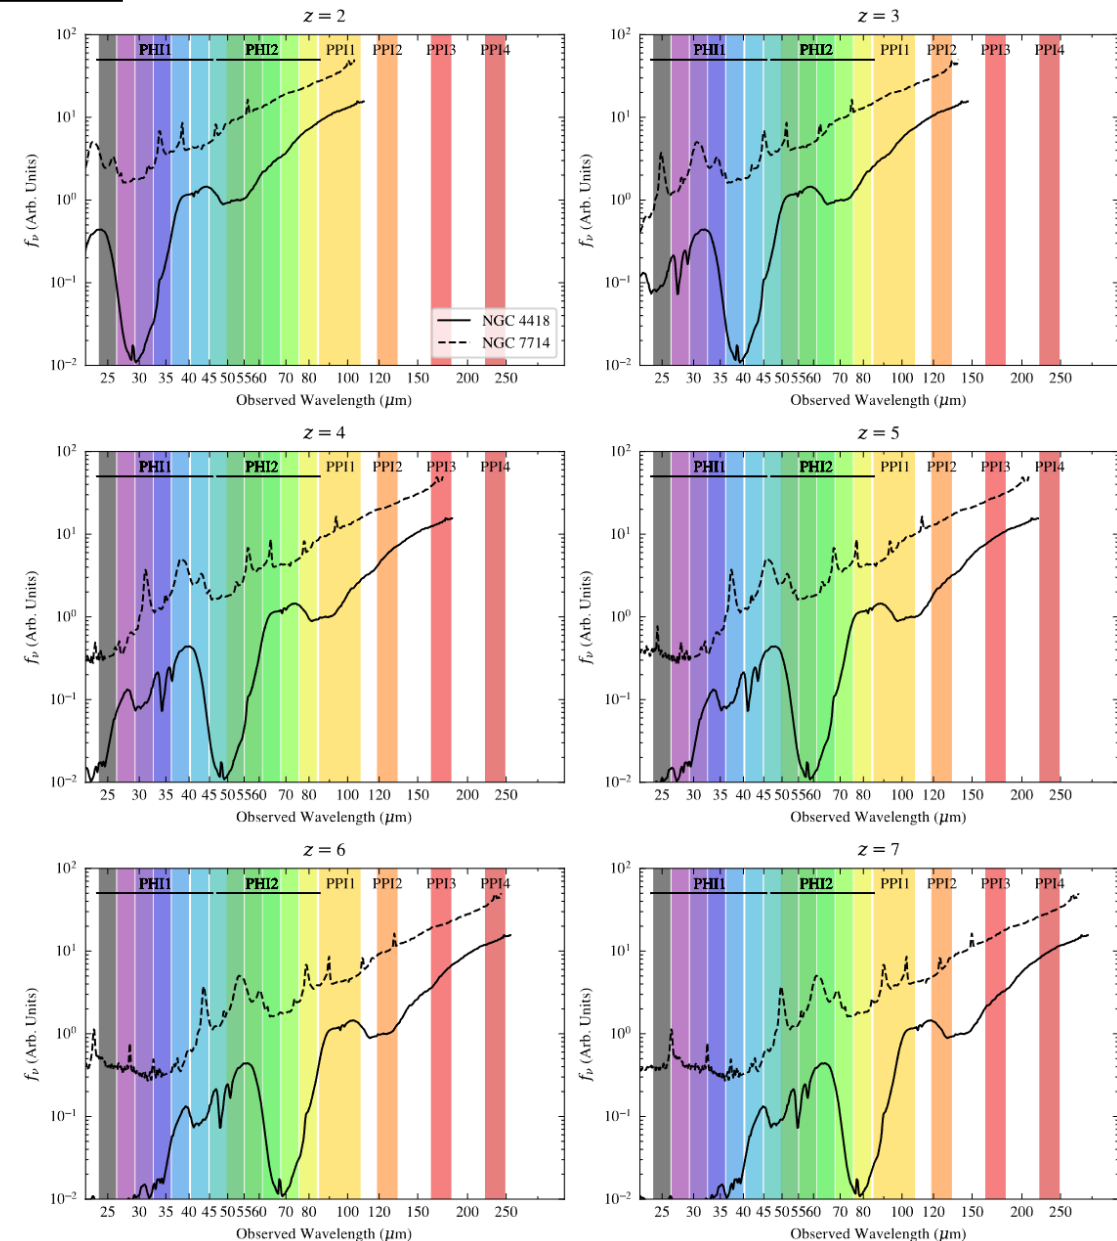

- Detect deep silicate with imaging
- JWST MIRI: $z \sim 0-3$
- PRIMA: $z \sim 2-7$

Obscured nuclei with PRIMA

- Select candidates via imaging surveys
- Obtain accurate phot-z using PAHs/silicate features
- Color selection and/or SED fitting to select candidates

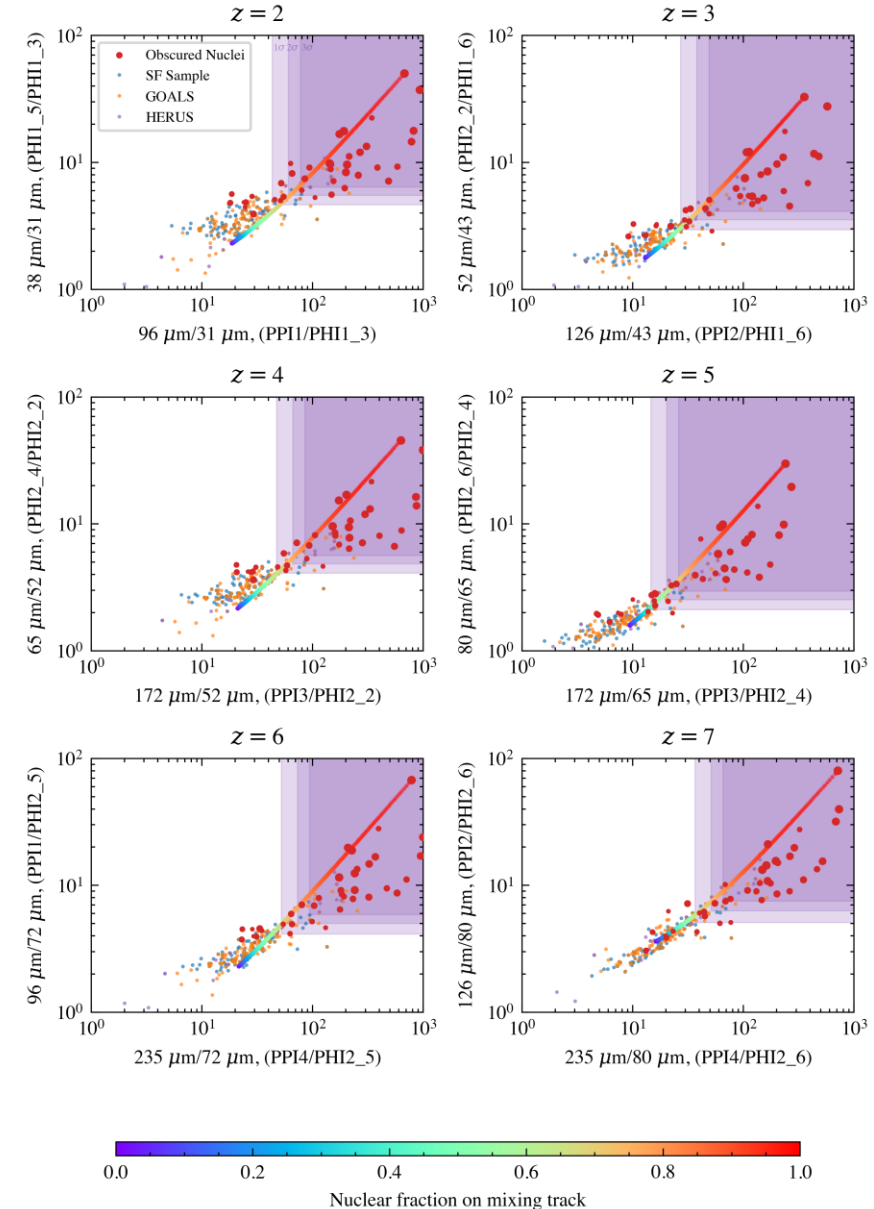

Donnan+25 (JATIS)

Obscured nuclei with PRIMA

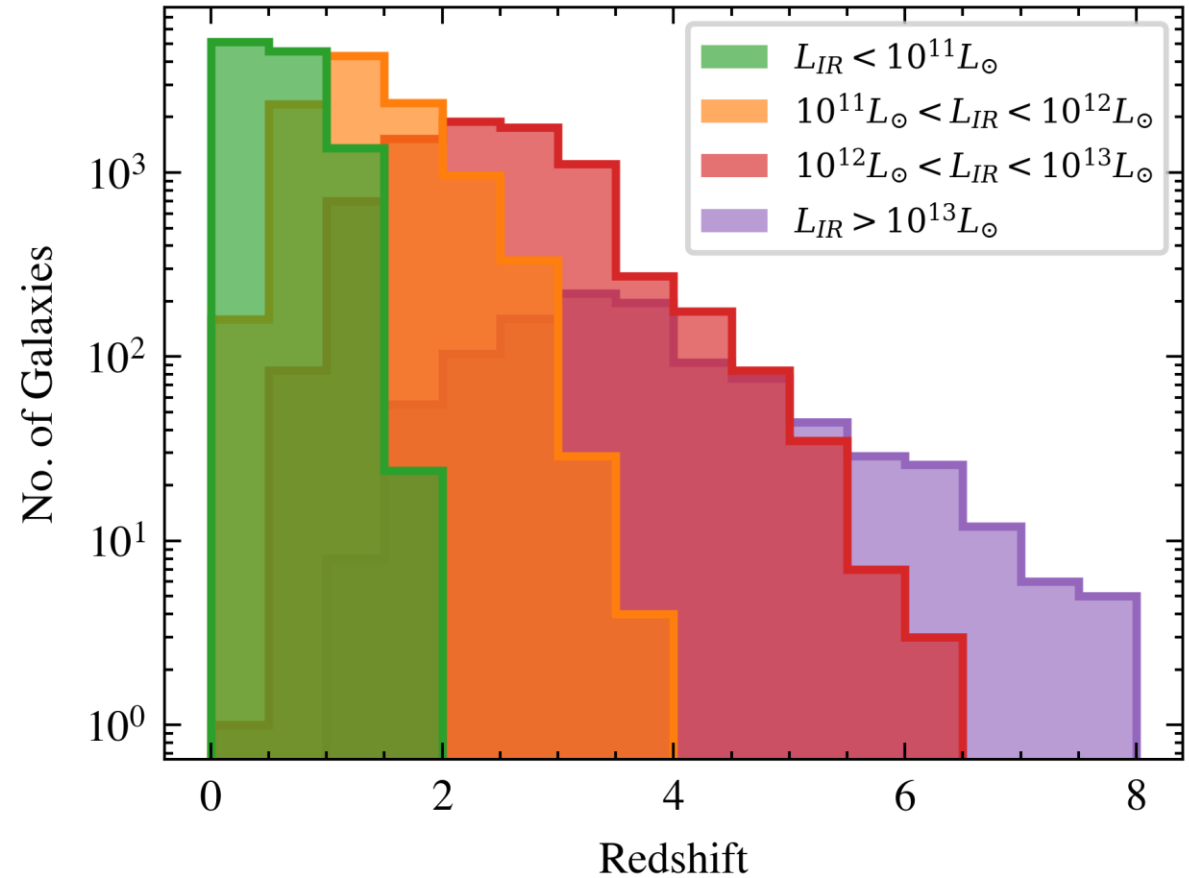

Donnan+25 (JATIS)

- Select candidates via imaging surveys
- Obtain accurate phot-z using PAHs/silicate features
- Color selection and/or SED fitting to select candidates

How many targets will PRIMAgger identify?

- 1500h/deg² survey using confusion mitigation techniques (Donnellan+24, talk later)
- SPRITZ simulation: generate galaxy catalogue from IR luminosity functions (Bisigello+21, 24)

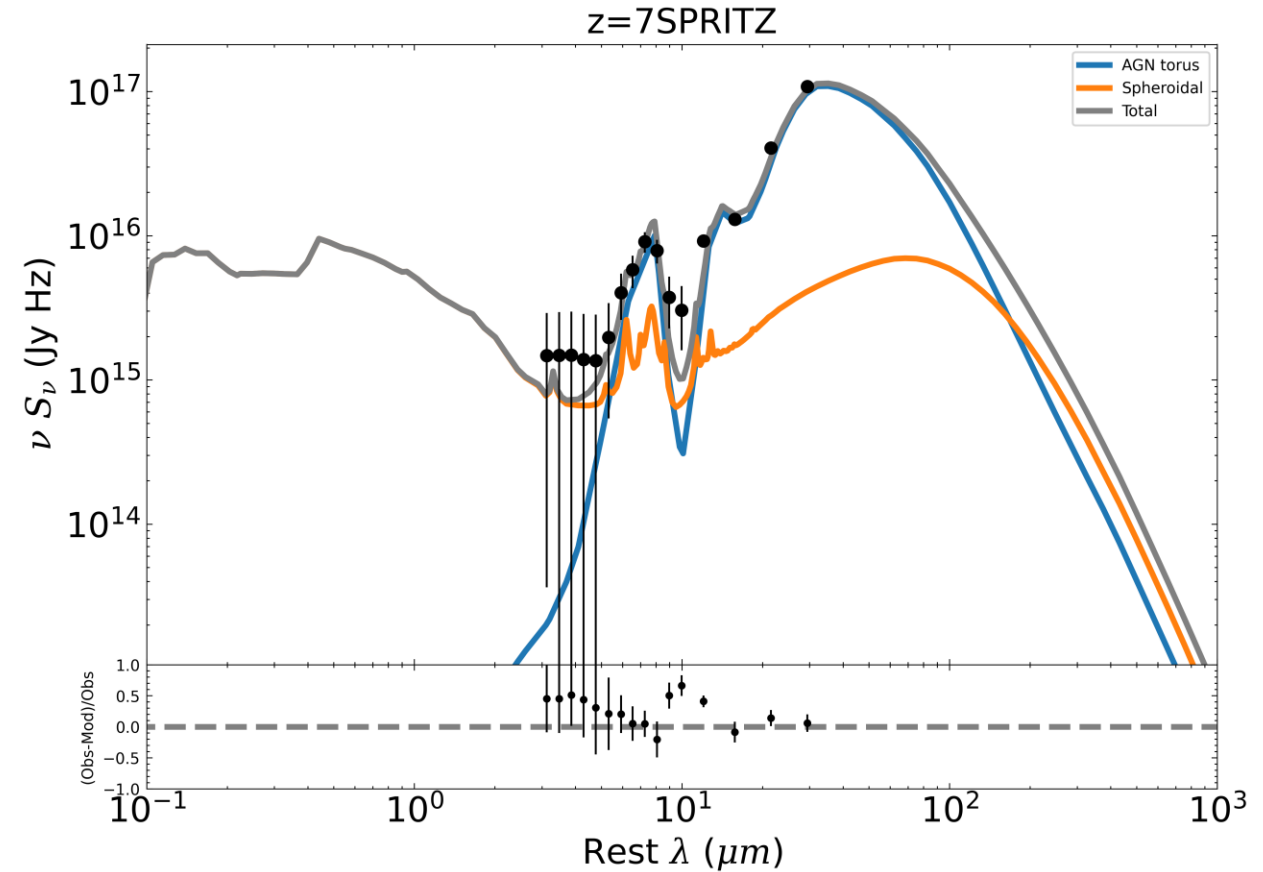

How many targets will PRIMAgger identify?

- 1500h/deg² survey using confusion mitigation techniques (Donnellan+24, talk later)
- SPRITZ simulation: generate galaxy catalogue from IR luminosity functions (Bisigello+21, 24)

PRIMAger

- High quality SEDs up to $z \sim 7$
- Constrain AGN torus models from SED fitting
- SMART SED Code (Varnava & Efsthathiou+24)

FIRESS Spectroscopy

- Follow-up spectroscopy of photometric candidates
- Identify ices, silicates, PAHs, ionic lines, molecular lines

Summary

- Identify Obscured Nuclei over cosmic time via mid-IR silicate absorption.
- PRIMAgger: 1000s-10s of obscured nuclei between $z \sim 2-7$
- FIRESS: high quality spectral follow-up with modest time investment
